

1. Program attached separately. This includes the files:

- my_dup2_test
- ReadMeQ4.md
- Makefile (used for q1 and q4 compiling)

2.

For **F_SETFD**, the file descriptor flag would be affected.

For **F_SETFL**, the file status flags would be affected, such as **O_APPEND**, **O_NONBLOCK**, **O_SYNC**, etc.

. Only **fd 1** would be affected by **SETFL** since it is only setting the descriptor flag of the one **fd**.

3. A hard link that gives the same inode number to files with different names. A soft link is a text string used as a shortcut by the operating to create a path to another file. With a soft link, there is a different inode between the file and the reference and if the original file is deleted, the soft link will no longer work.

For example, consider if you have a file called **King.txt**.

- 1) If you want to create a hard link, you can use the command ``ln King.txt King_copy.txt``

```
[hertz@csnode-02 ~]$ ln King.txt King_copy.txt
[hertz@csnode-02 ~]$ ls
apue.3e      hw1-hertz.txt      hw2-hertz.txt  Lab1      src.3e.tar.gz
bashrc       hw2_1_AH.txt       hw3_AH        Lincoln.txt tmp
csci3751     hw2_2_AH.txt       Kennedy.txt    Makefile  typescript
DSPD         hw2_3_AH.txt       King_copy.txt Networks
find-result  hw2-hertz-script-4.txt King.txt      OOP
```

King_copy.txt is now the same file as King.txt and points to the same inode.

2) Now, create a soft link to a new file named King_symbolic_copy.txt. Use the command 'ln -s King.txt King_symbolic_copy.txt'.

```
[hertz@csnode-02 ~]$ ln -s King.txt King_symbolic_copy.txt
[hertz@csnode-02 ~]$ ls
apue.3e      hw2_1_AH.txt      Kennedy.txt      Makefile
bashrc       hw2_2_AH.txt      King_copy.txt    Networks
csci3751     hw2_3_AH.txt      King_symbolic_copy.txt OOP
DSPD         hw2-hertz-script-4.txt King.txt        src.3e.tar.gz
find-result  hw2-hertz.txt     Lab1            tmp
hw1-hertz.txt hw3_AH            Lincoln.txt      typescript
```

3) Remove the original file using the command 'rm King.txt'

```
[hertz@csnode-02 ~]$ rm King.txt
[hertz@csnode-02 ~]$ ls
apue.3e      hw2_1_AH.txt      Kennedy.txt      Networks
bashrc       hw2_2_AH.txt      King_copy.txt    OOP
csci3751     hw2_3_AH.txt      King_symbolic_copy.txt src.3e.tar.gz
DSPD         hw2-hertz-script-4.txt Lab1            tmp
find-result  hw2-hertz.txt     Lincoln.txt      typescript
hw1-hertz.txt hw3_AH            Makefile
```

4) Run 'cat King_copy.txt' and you will be able to still view the contents of the file even though the original file was deleted.

5) Run 'cat King_symbolic_copy.txt'

You will receive a "No such file or directory" error.

```
[[hertz@csnode-02 ~]$ cat King_symbolic_copy.txt
cat: King_symbolic_copy.txt: No such file or directory
```

This exercise demonstrates the difference between a hard and soft link.

4.

1) The `rmdir()` command does succeed.

2) When the program tries to read the current directory, it is able to open that directory, because you set the current working directory (cwd) there, which is remembered by the kernel and the directory won't entirely go away until it is no longer the cwd. For example, if I go to the directory `foo` so that it is the cwd, and then I delete it, if I check what the cwd is, the kernel still remembers, it just shows it as deleted.

```
[[hertza@csci-gnode-03 tmp]$ cd foo
[[hertza@csci-gnode-03 foo]$ ls -la /proc/self/cwd
lrwxrwxrwx 1 hertza hertza 0 Mar 30 10:48 /proc/self/cwd -> /tmp/foo
[[hertza@csci-gnode-03 foo]$ rmdir /tmp/foo
[[hertza@csci-gnode-03 foo]$ ls -la /proc/self/cwd
lrwxrwxrwx 1 hertza hertza 0 Mar 30 10:49 /proc/self/cwd -> /tmp/foo (deleted)
```

3) Program is found in the file `q4.c`, along with a makefile and `ReadMeQ4`. Here is the expected output (also found in the `ReadMe`).

```
[[hertza@csci-gnode-03 hw3_AH]$ ./q4
running
folder removed successfully
opened directory with .
could not open directory using ../foo
could not open directory using /tmp/foo
```

5. The purpose of both `fflush()` and `fsync()` is to write data. However, as a C library function, `fflush(aFilePointer)` is part of the stdio library, which operates on the file structure. The `fsync(2)` system call operates on the kernel and can tell the OS that it needs a buffer on the hardware storage.

If you ran these two in succession, the output stream would be written to a buffer that is associated to the operating system first when you ran `fflush()`.

Then, `fsync(fileno(aFilePointer))` would cause the OS to write a buffer to your physical media.
